

Optical Methods for Medical Imaging and Diagnosis

Warren Grundfest, Zach Taylor

UCLA, CASIT

Optical techniques play a major role in modern medical diagnostics through imaging and spectroscopy

Typical examples include endoscopic inspection of the GI tract and measurement of Oxygen concentration in the blood based on hemoglobin absorption

Recent advances in technology have improved both the optical diagnostic and imaging capabilities for a wide variety of applications

Near Infrared Spectroscopy (NIRS) – Promises and Pitfalls

Goals

1. Current Status of NIRS Devices.
2. Limitations in NIRS Monitoring Technologies.
3. Visible Light Approaches.

Neonatal Oxygen Therapy

Problems Related to Oxygen Therapy

- Hyperoxia-induced Oxygen Toxicity
- *'Acute' Toxicity – "Bert Effect"*
 - Patient is exposed to very high concentrations of oxygen for short durations
 - Ex: CO poisoning, respiratory distress of newborns, etc.
 - Primarily CNS effects due to oxidation and polymerization of –SH groups of enzymes, resulting in cellular damage.
- *'Chronic' Toxicity – "Smith Effect"*
 - Low concentrations of oxygen are administered but for longer duration
 - Primarily has pulmonary effects
 - High oxygen conc. may damage the pulmonary epithelium, inactivate the surfactant and thus lead to atelectasis.

Problems Related to Oxygen Therapy

- Retinopathy of Prematurity (ROP)
- ROP, fka retrolental fibroplasia, is one of the single largest causes of blindness in childhood.
- Pathology: High oxygen concentration induces vasoconstriction, especially in the temporal portion of the retina.

Problems Related to Oxygen Therapy

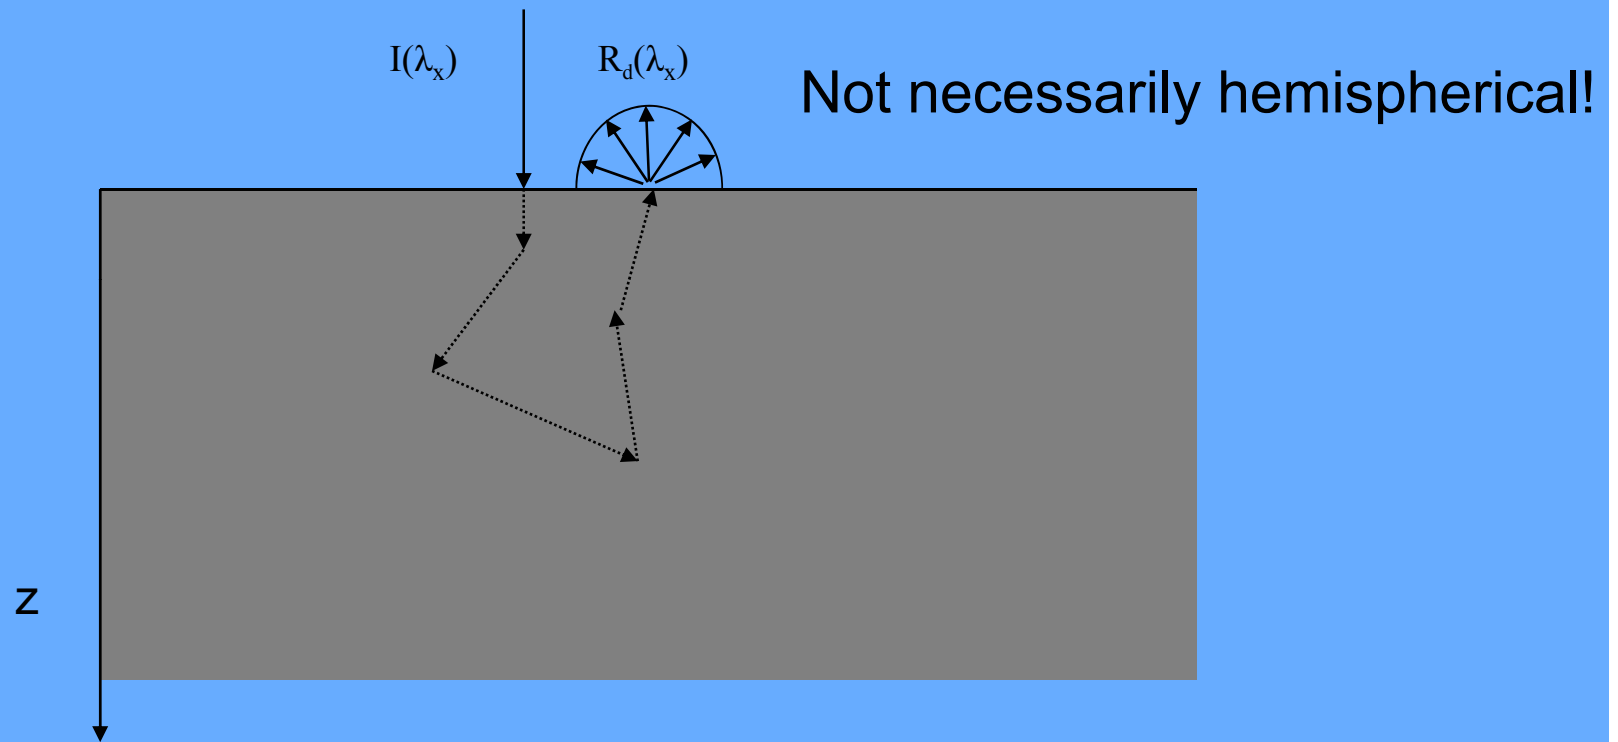

- Retinopathy of Prematurity (ROP)
- Pathology (continued)
 - After the cessation of oxygen therapy, regeneration of the vessels occurs extending into the vitreous past the retina.
 - Dilation and rupture of these vessels can cause blindness due to:
 - Vitreous or retinal hemorrhage;
 - Fibrosis;
 - Adhesions leading to retinal detachment.

Possible Solutions to Problems Related to Oxygen Therapy

- Continuous Measurement of Cerebral Oxygen Saturation Levels.
- Continuous Measurement of SpO₂ Levels.
- Use of Non-invasive Devices Preferred!

Theoretical Basis for Optical Measurements

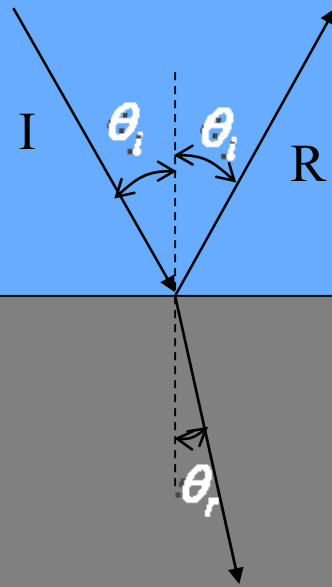

Basics of Light Transfer

Diffuse reflectance spectroscopy.

Given the reflected light, determine the optical properties of the medium.

Boundary Effects

Fresnel's equation for normal incidence

$$R = \left(\frac{n_{\text{tissue}} - n_{\text{air}}}{n_{\text{tissue}} + n_{\text{air}}} \right)^2$$

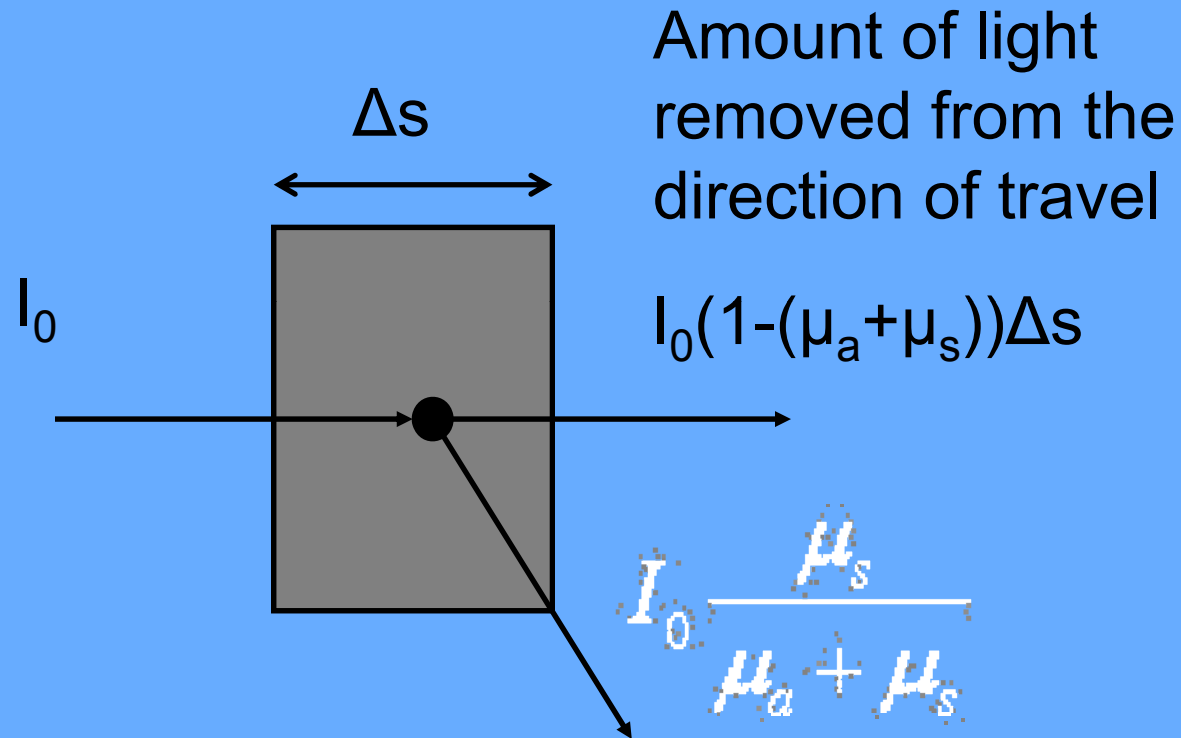

Snell's law

$$\frac{\sin \theta_i}{\sin \theta_r} = \frac{v_{\text{air}}}{v_{\text{tissue}}} = \frac{n_{\text{air}}}{n_{\text{tissue}}}$$

Specular reflectance, R , is usually removed with a polarized filter.

Source: *M.F. Modest.*

Absorption and Scattering

Idealized photon/media interaction

Scattering

Scattering phase function determines the probability of scattering in a given direction.

Henyey-Greenstein - Approximation

$g = 0.00$

$g = 0.20$

$g = 0.90$

$g = 1.00$

$$p(\theta) = \frac{1}{4\pi} \frac{1-g^2}{(1+g^2-2g\cos(\theta))^{3/2}}$$

Source: *Henyey, L.G., Greenstein, J.L.*

Reduced Scattering Coefficient

Incorporates the effects of anisotropy: $\mu_s' = \mu_s(1 - g)$

Scattering plays no role

$$g = 1$$

Reduced Scattering Coefficient

Incorporates the effects of anisotropy: $\mu_s' = \mu_s(1 - g)$

Scattering has maximum effect

$$g = 0$$

Summary of Optical Properties

Attenuation due to heat generation

μ_a

Attenuation due to scattering
accounting for anisotropy

μ_s'

1/cm

Attenuation due to scattering

μ_s

Single scattering albedo

$$\omega = \frac{\mu_s}{\mu_a + \mu_s}$$

Total attenuation

$$\beta = \mu_a + \mu_s$$

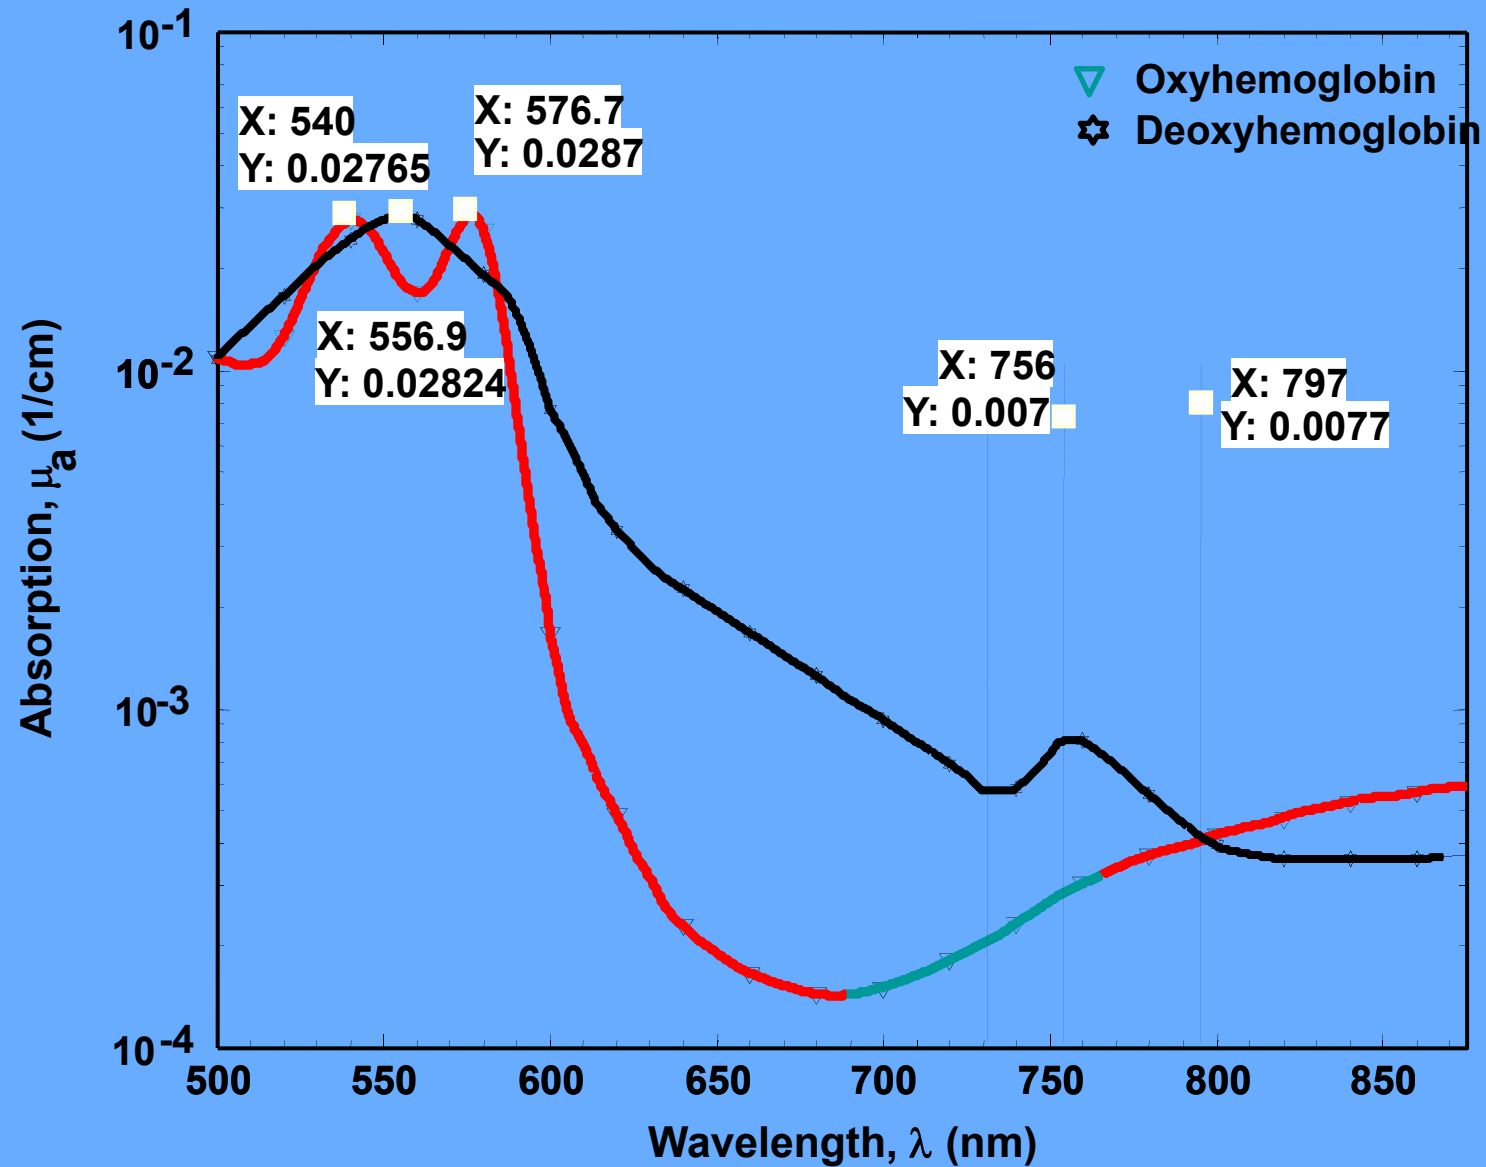

Anisotropy of scattering

g

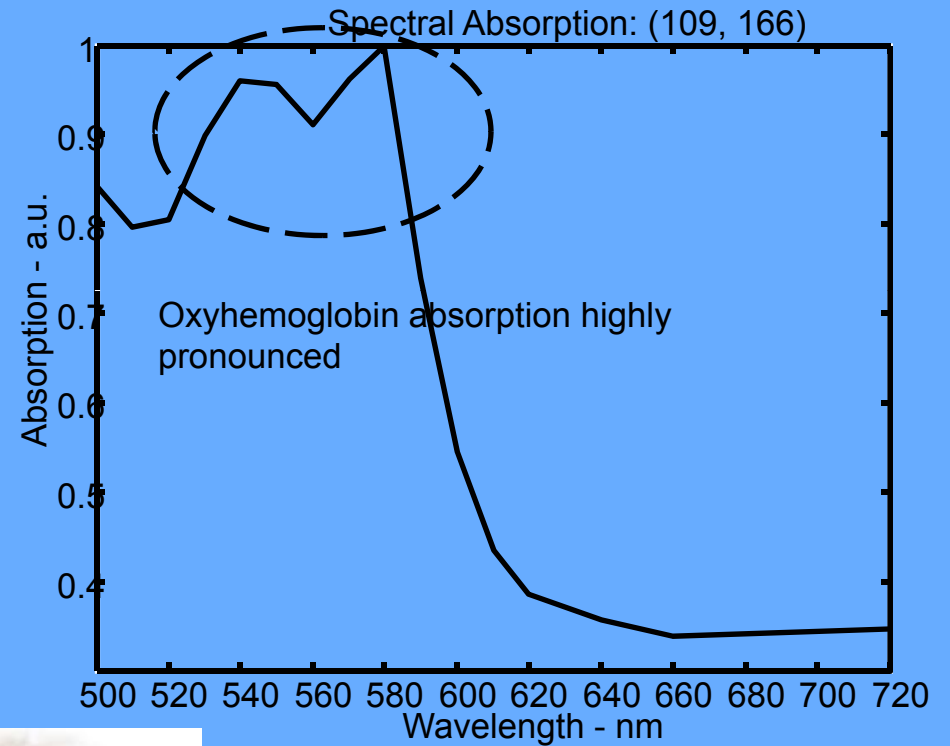

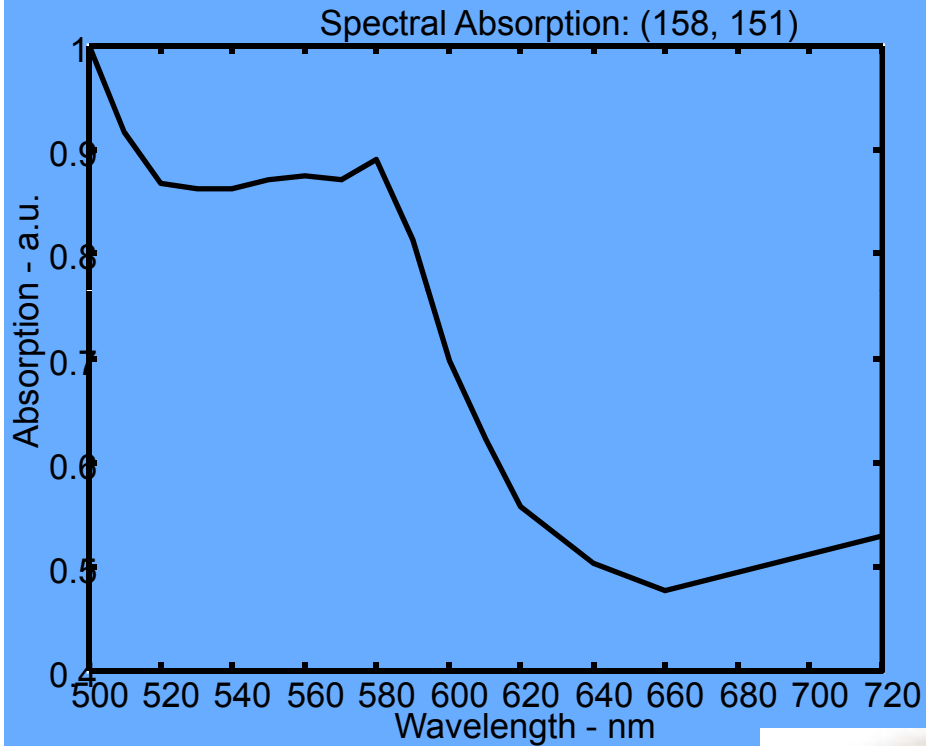

Index of refraction

n

Absorption and Blood

Deferent Oxygen Saturations

Diffusion Approximation (DA)

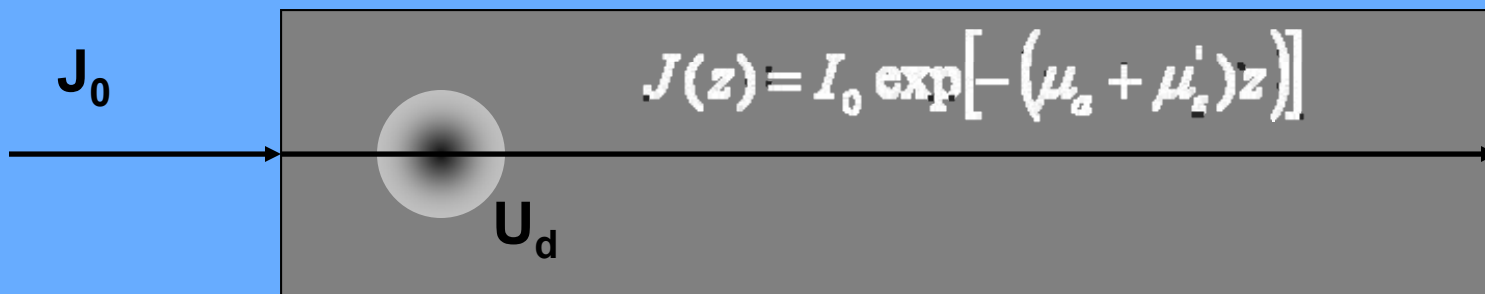

Effective diffuse flux

$$\frac{d^2 U_d(z)}{dz^2} - \kappa_d^2 U_d(z) = \frac{3}{4\pi} \frac{\mu'_s}{\mu_a + \mu'_s} J_0 \exp[-(\mu_a + \mu'_s)z]$$

BL's law source term

$$\kappa_d = 3\mu_a(m\mu_a + m\mu'_s) \quad \mu'_s = \mu_s(1 - g)$$

Reduced scattering coefficient

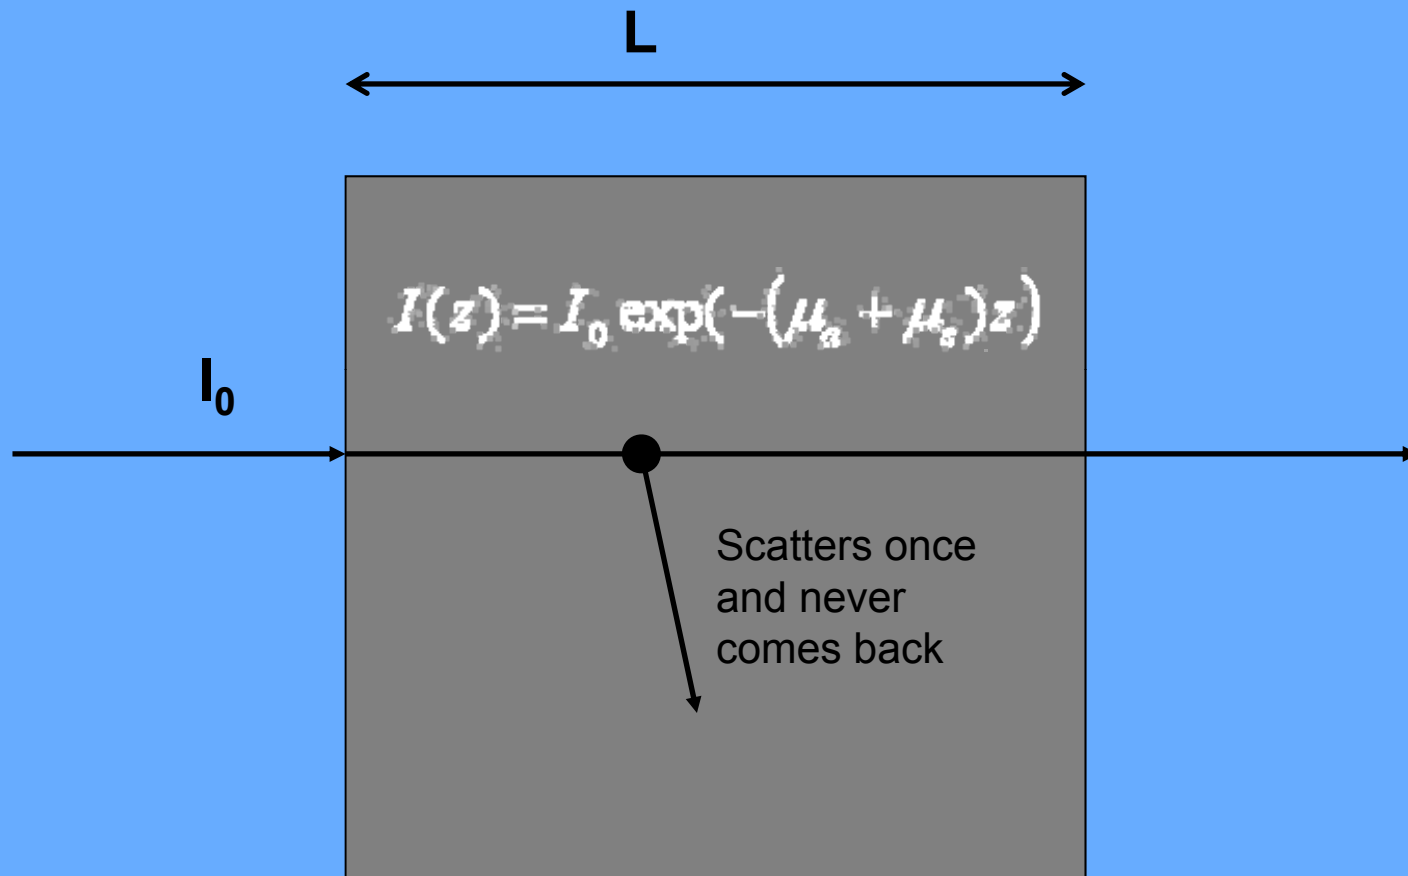

Application of DA

- Determine μ_a and μ'_s . Both carry biological significance.
- Absorption coefficient used to determine hemoglobin saturation.
- Scattering properties hold biological information about tissue structure.
- Time resolved formulation also exists.

Limitations of DA

- Model assumptions are not always valid.
- Difficult to formulate for multi-layer systems.
- Boundary conditions at interfaces complicate analysis.

Beer-Lambert's (BL's) Law

Attenuation coefficient: $\ln \frac{I(L)}{I_0} = -(\mu_a + \mu_s)L$

Modified BL's Law

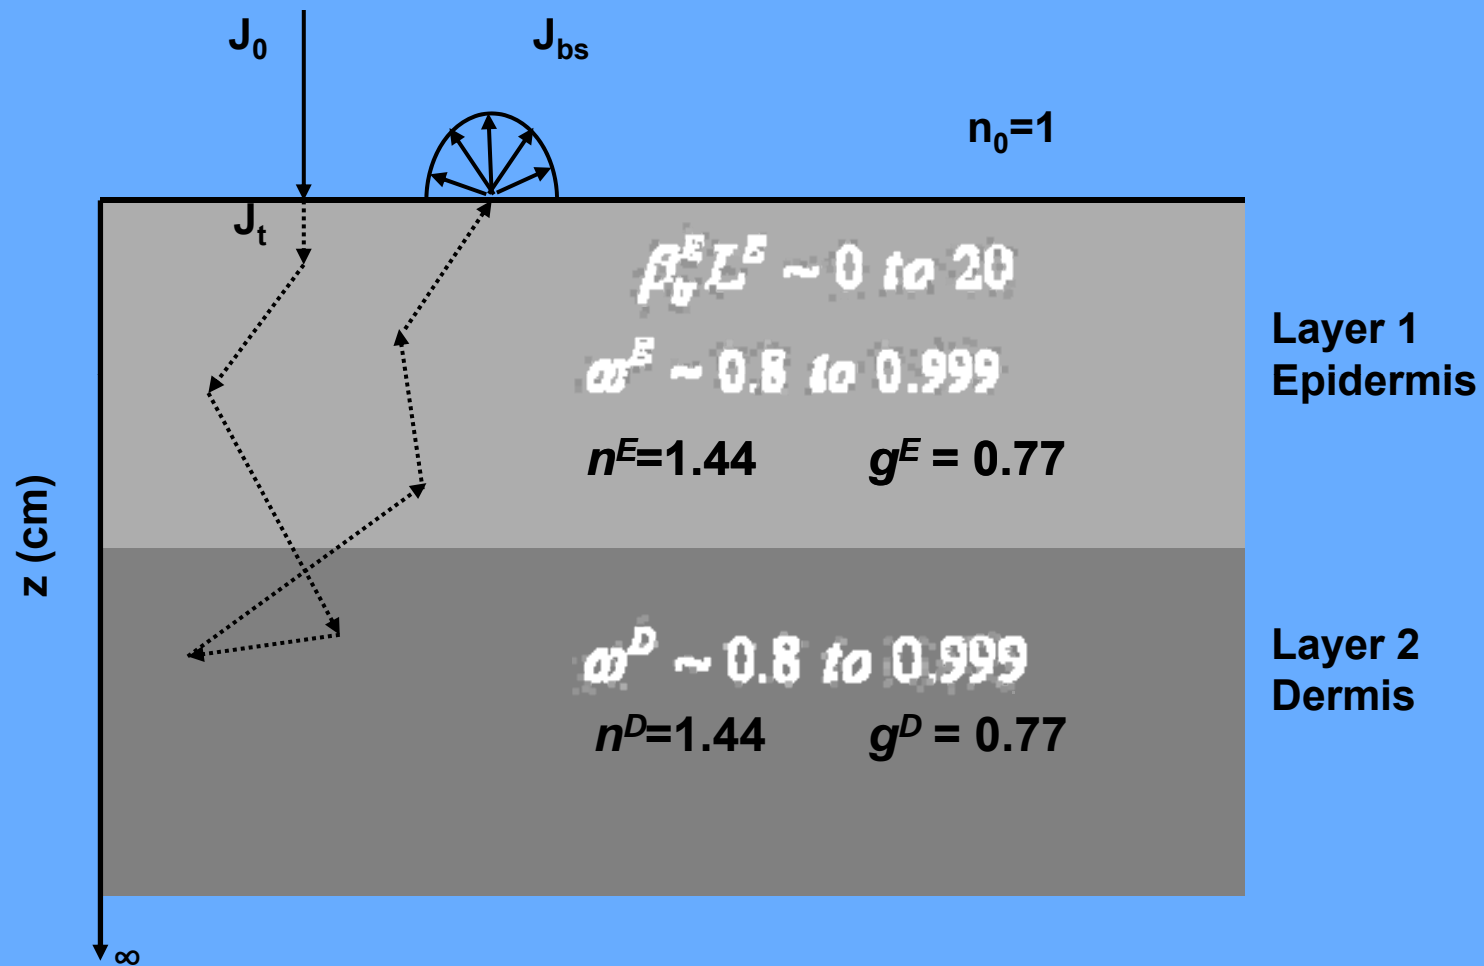

Application of Modified Beer's Law

- Determine absorption coefficient at several wavelengths.
- Fit absorption spectra of hemoglobin to the observed.
- Thus determine hemoglobin saturation.

Limitations of Modified BL's Law

- Information about scattering is lost
 - Hard to interpret G in a physical manner;
 - Changes in blood volume cannot be observed;
 - Modified BL assumes a fairly constant optical system.
- Good for detecting change in oxy/deoxy levels.

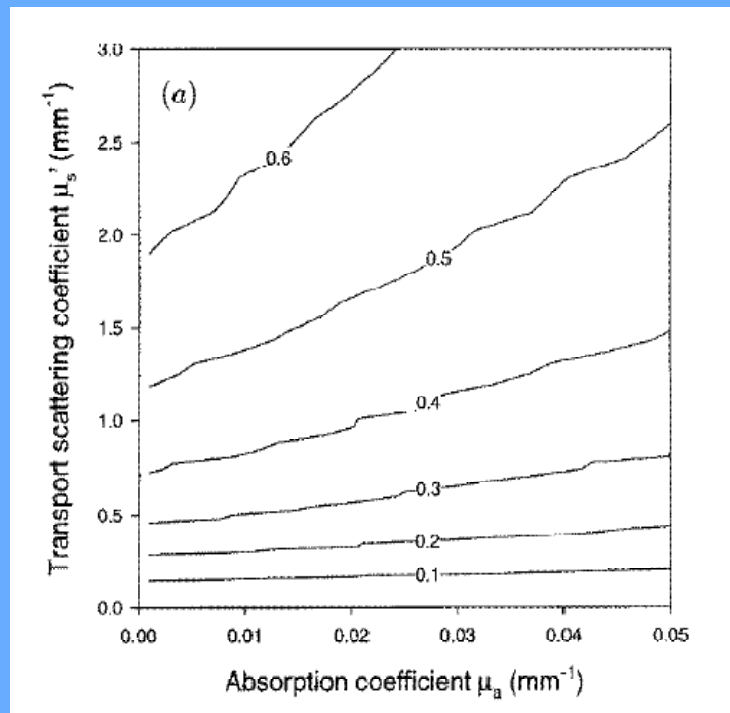

Monte Carlo (MC) Methods

Reduced optical thickness of epidermis: $\beta_{0r}^E L^E = L^E (\mu_a + \mu_s')$

Monte Carlo Simulations

Perform multiple simulations of experimental setup with different samples.

Use this look up table to infer optical properties from measured data.

Source: Simpson, CR.

Monte Carlo Limitations

- Simulation is limited to particular g and n .
- Empirical method hard to interpret and modify without rerunning the experiment.
- Models generally single layer and insufficient for *in vivo* use.
- Current research is expanding MC

Summary of Theoretical Models

- Various predictive equations have been developed to extract information from optical signals.
- Measurement of scattering and absorption can provide quantitative information about Hb oxygenation and concentration.
- Theoretical models provide a framework for algorithm development and device operation.
- Continuing development of models has the potential to improve the accuracy and spatial resolution of optically derived information.

Current NIRS Devices for Cerebral Oxygen Monitoring in Neonates

NIRS Devices in Neonatal Oxygen Monitoring

- Definitions
 - Infrared (IR) – light with wavelength between 750nm and 1mm.
 - Near IR (NIR) – infrared light with wavelength between 750nm and 1400nm.
 - NIRS – near-infrared spectroscopy.
 - VV – veno-venous.
 - ECMO – extracorporeal membrane oxygenation.
 - SctO₂ – cerebral tissue oxygen saturation.
 - SvO₂ – cerebral venous oxygen saturation

NIRS Devices in Neonatal Oxygen Monitoring

- NIRS in Neonatal Patients:
 - Used to Study Cerebral Hemodynamics and Oxygenation.
 - Non-invasive, high temporal resolution, relatively easy to use.
- Types of Measurements:
 - Regional Cerebral Tissue Oxygen Saturation (rSO_2).
 - Absolute Cerebral Tissue Oxygen Saturation.

NIRS Devices in Neonatal Oxygen Monitoring

NIRS Devices in Neonatal Oxygen Monitoring

INVOS[®] 5100C Cerebral Oximeter

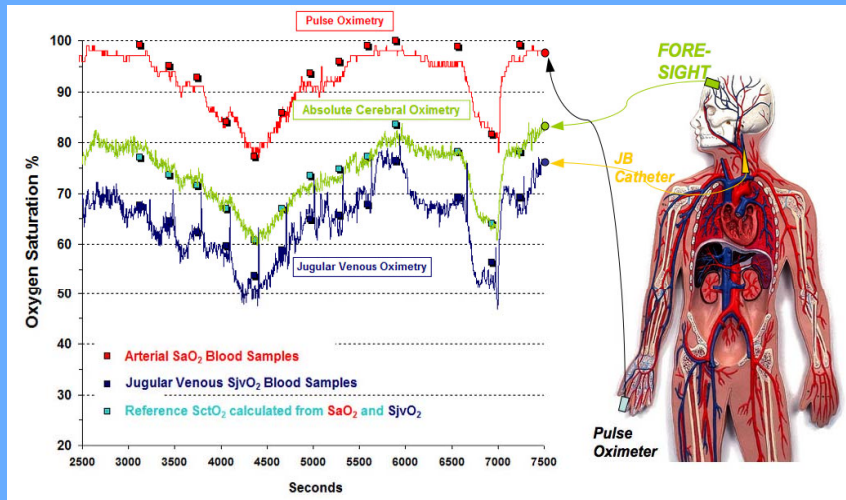

- Near-infrared light at wavelengths of 730 nm and 810 nm.
- Emitted from a source on one side of disposable sensor.
- The light gets scattered in biological tissue (mainly gray matter).
- The remaining light is detected by detectors on the other side of disposable sensor.

Source: Somanetics Corporation (www.somanetics.com)

NIRS Devices in Neonatal Oxygen Monitoring

FORE-SIGHT[®] MC2000 Cerebral Oximeter

- Light is projected into the brain in four precise wavelengths - 690, 780, 805, and 850 nm.
- It could reduce patient dependent variability (e.g. Melanin).
- More reliable measurements in low or zero perfusion states.
- Source: *CASMED Medical Systems, Inc. (www.casmed.com)*
- No user calibration required.

Visible Light Oxygen Saturation Detection

Visible Light Oxygen Saturation Device

- T-STAT 303
- Manufacturer: Spectros, Portola Valley, CA
- Use visible light (470 nm to 600 nm range)
- Report capillary-weighted oxygen saturation due to the selection of the range of light emitted
- Hemoglobin has the strongest absorbance in 475 nm – 600 nm range. In capillaries, a large amount of light passed through capillary structures can be scattered back to the sensor.

T-Stat Comparison

rainbow™

Conclusions on Alternative Technologies

- Current NIRS technology suffers from motion artifact and measurement error.
- Capnographic measurements are effectively performed by currently approved devices.
- Peripheral SpO₂ measurements form the basis of current management
- Research objectives include improved spatial localization & measurement accuracy, and reduction of artifacts.

**SEVERAL TECHNOLOGIES ARE
DRAMATICALLY CHANGING THE
FACE OF HEALTHCARE**

**ADVANCES IN IMAGING ARE THE
FOUNDATION FOR THE DEVELOPMENT
OF NEW MINIMALLY INVASIVE
THERAPIES**

Applications of Optical Technologies are expanding the capabilities of traditional medical imaging devices

New imaging modalities provide the physician with unique methods of identifying normal and diseased tissue.

Optical biopsy techniques may permit real time analysis of tissue without removing it from the body.

Current Methods include:

- **direct inspection**
- **Rigid endoscopy**
- **Flexible endoscopy**
- **“Pill cam”**

DEFINITIONS

The word **ENDOSCOPY** is derived from the Greek by combining the prefix **"ENDO"** = **"WITHIN"** and the verb **"SKOPO"** = **"TO VIEW WITH A PURPOSE"**.

It is exactly this "observation with intent" which is the goal of Endoscopy. This intent can be diagnostic and/or therapeutic.

An **ENDOSCOPE** is an instrument for examining the "within", (bodily canals or hollow organs)

CLASSIFICATION OF ENDOSCOPES - 1

ACCORDING TO THEIR USE

INDUSTRIAL

Inspection of inaccessible or hazardous areas

MEDICAL

Diagnostic and/or therapeutic procedures

ACCORDING TO MECHANICAL RIGIDITY

RIGID

FLEXIBLE

HYBRID

Incorporate shafts with both rigid & flexible areas

ACCORDING TO DURABILITY

Optical Engineering (Lens Design)

Mechanical Engineering

Material Science (glasses, semi-conductors, biocompatible materials)

Video/Electronics Engineering (Camera design, documentation equipment)

Imaging Science

BASIC CONSTRUCTION OF AN ENDOSCOPE

THE EVOLUTION OF MINIMALLY INVASIVE SURGERY

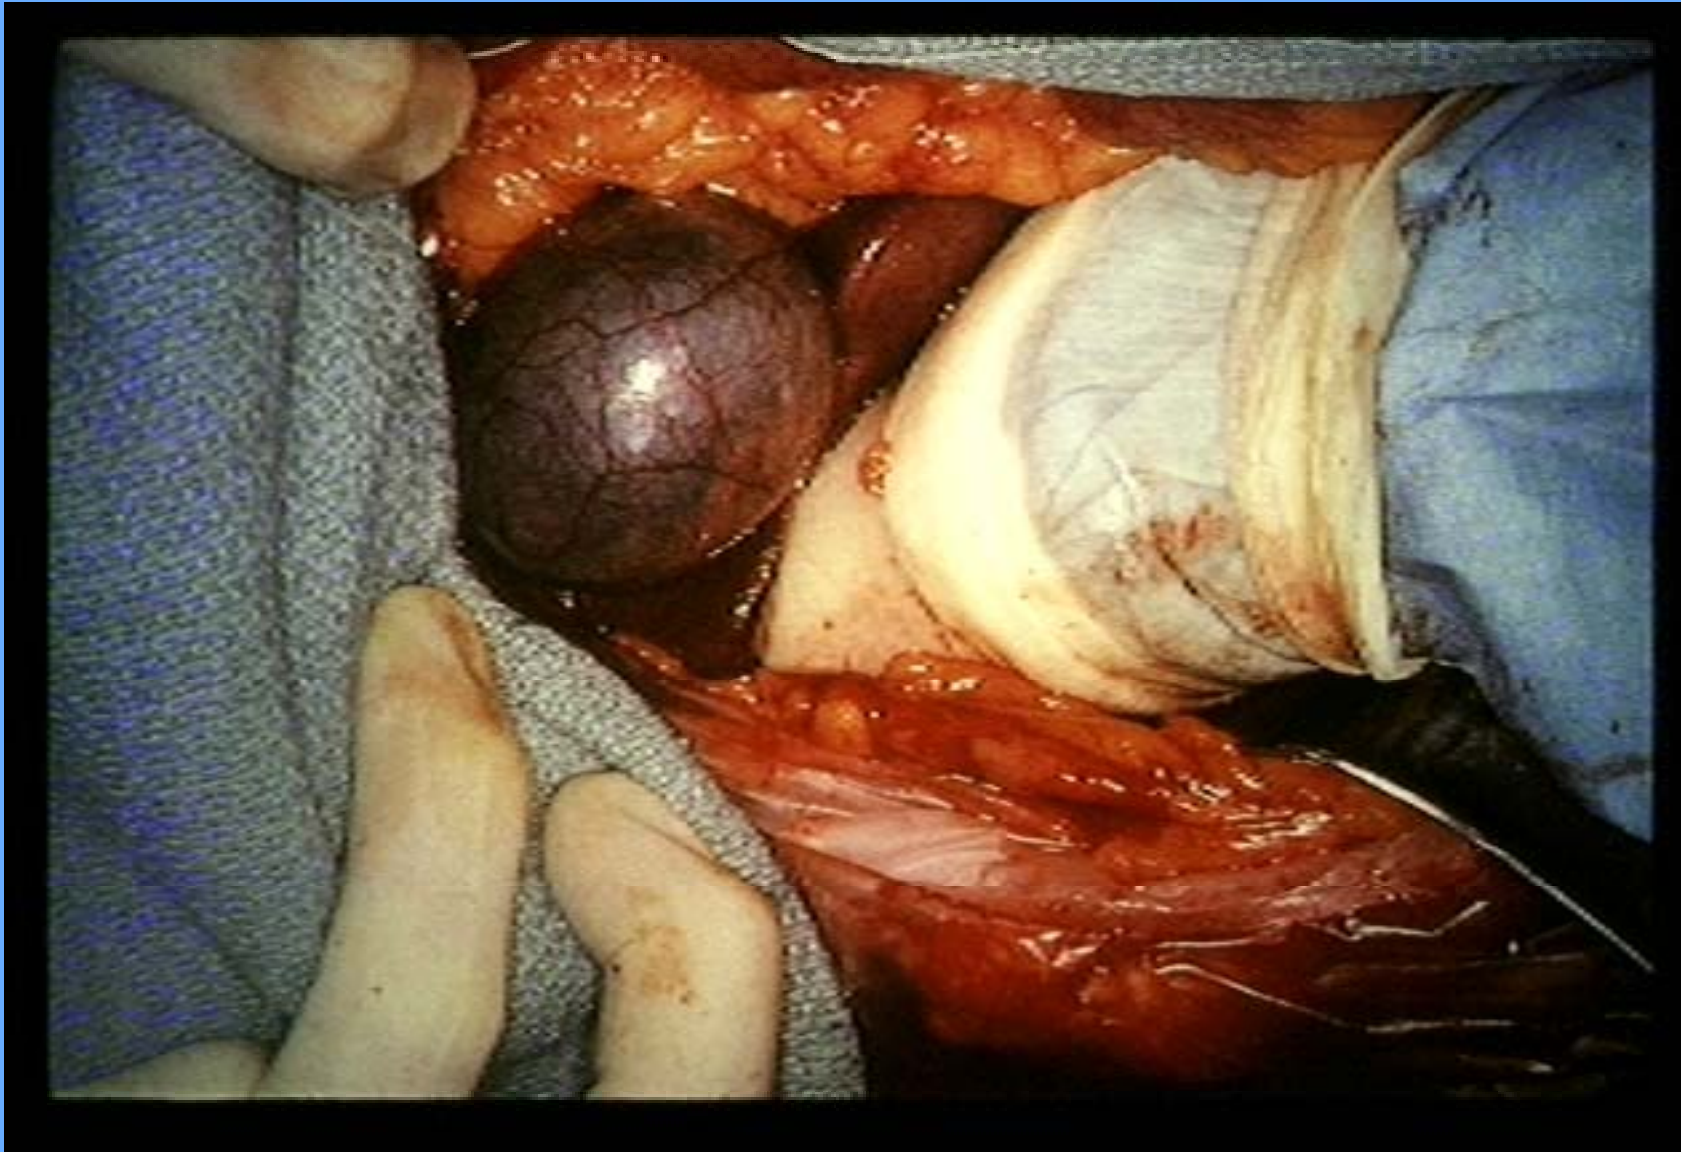

FOR MORE THAN 150 YEARS, LARGE INCISIONS INTO BODY CAVITIES WAS THE ONLY MEANS OF ACCESSING DISEASED ORGANS. IN THE LATE 1970'S, INTERVENTIONAL TECHNIQUES USING X-RAY IMAGING ALLOWED PHYSICIANS TO OPEN BLOCKED ARTERIES WITHOUT LARGE INCISIONS.

THE EVOLUTION OF MINIMALLY INVASIVE SURGERY

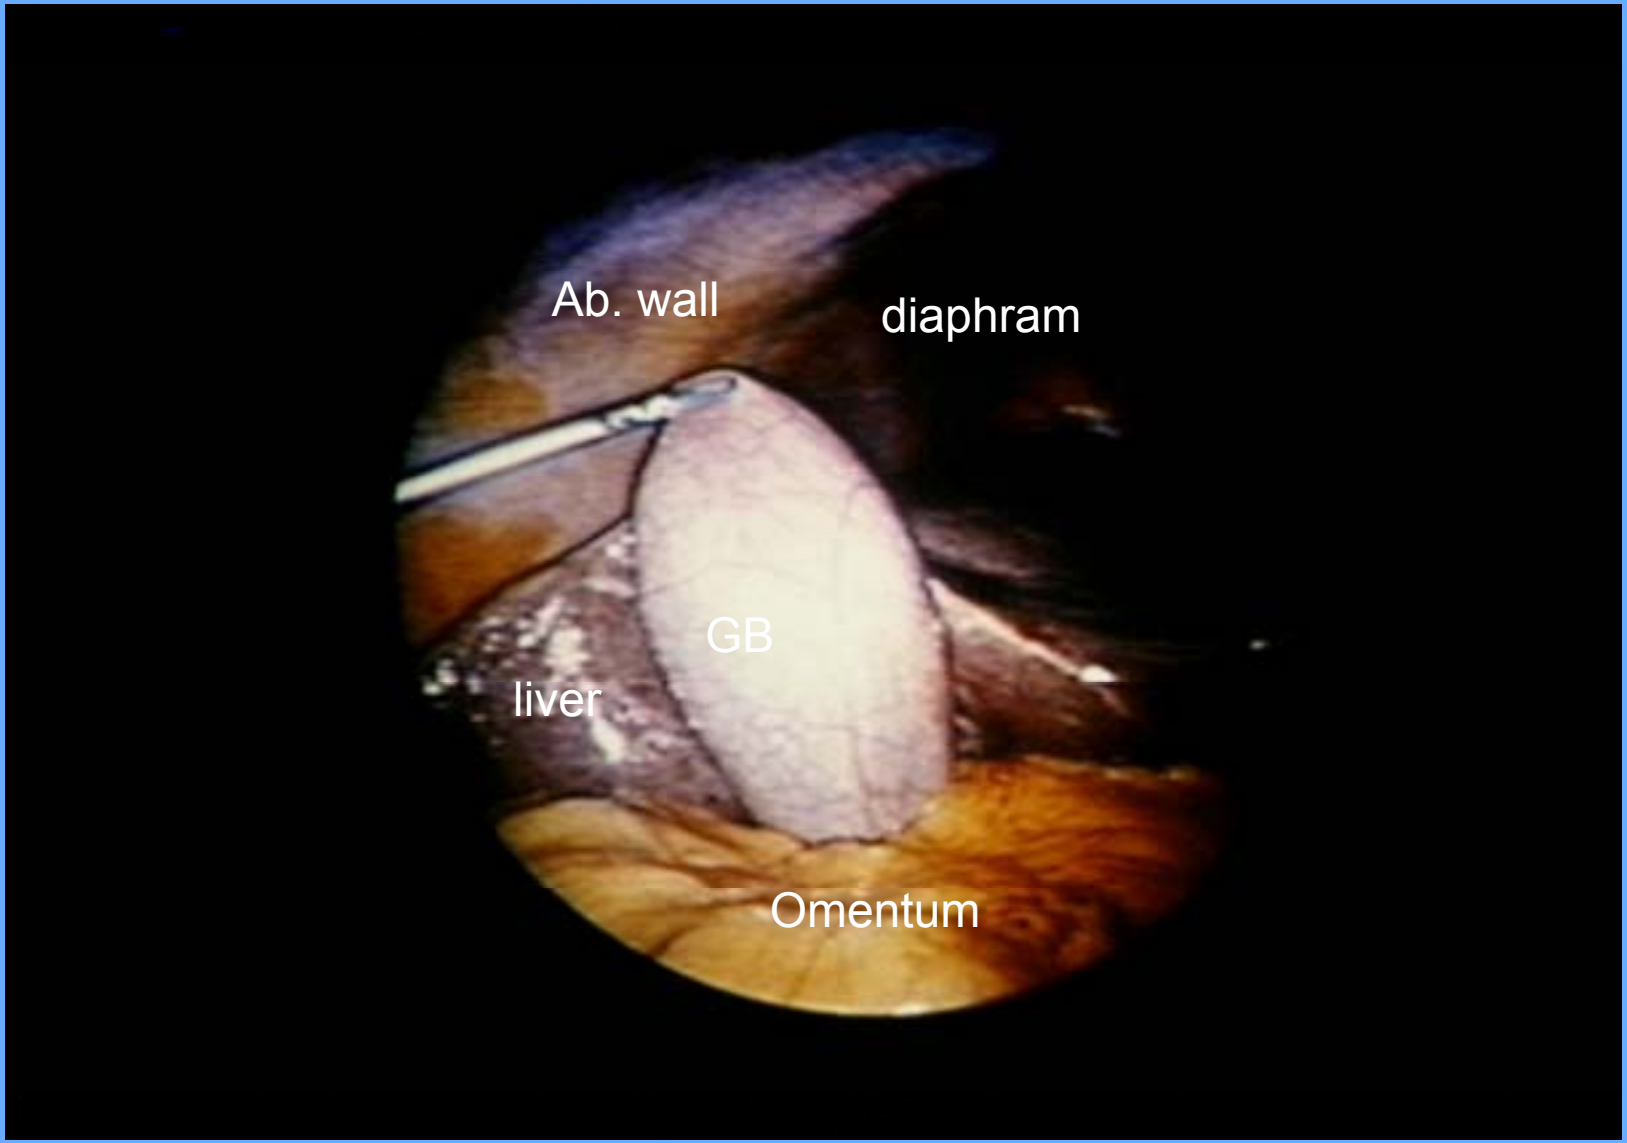

IN THE EARLY 1980'S, VIDEO IMAGING THROUGH ENDOSCOPES BECAME FEASIBLE, ALLOWING THE ENTIRE SURGICAL TEAM TO SEE INSIDE THE BODY.

IN THE MID 1980'S, INSTRUMENT MAKERS BEGAN TO DEVELOP TOOLS TO WORK WITH THE OPTICAL IMAGING SYSTEMS AT OPERATIVE SITES WITHOUT LARGE INCISIONS.

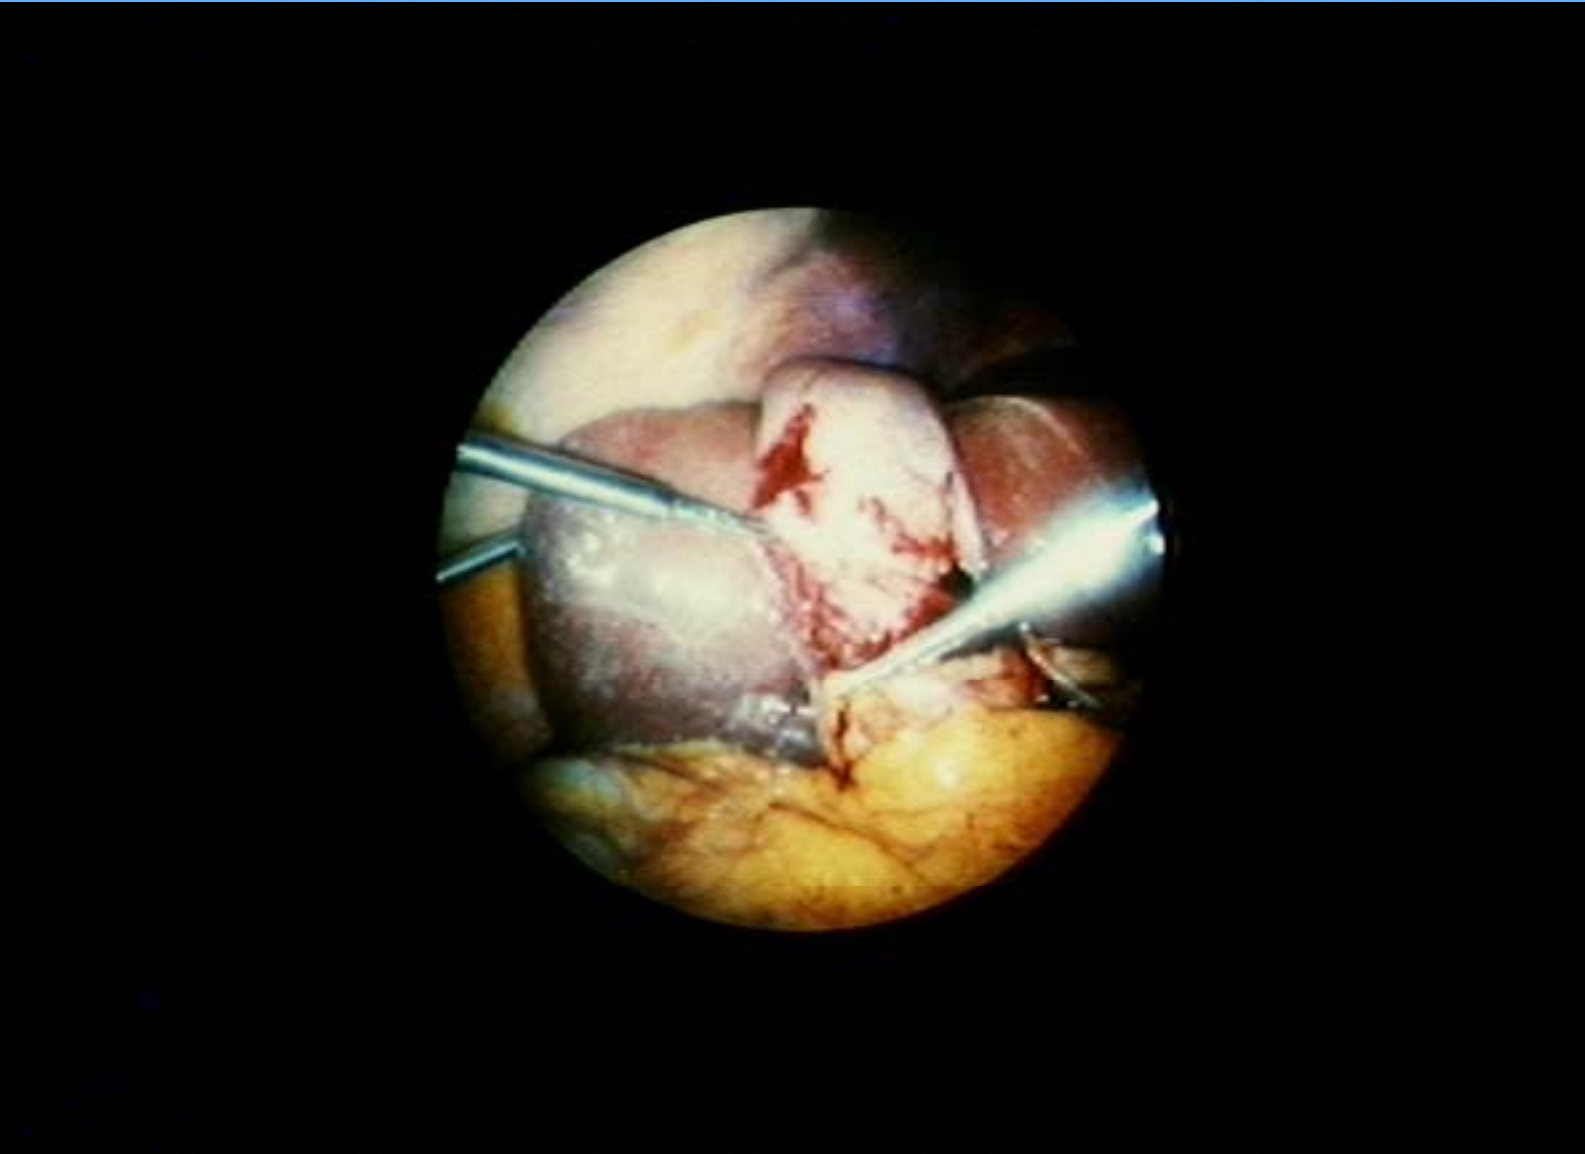

Ab. wall

diaphragm

 $d < D$ (Smaller Diameter)
 $b > B$ (Higher Brightness)

FIBEROPTICS

Core Refractive Index $>$ Clad Refractive Index

Optical radiation is trapped in the cylindrical core due to Total Internal Reflection at the core clad interface.

Numerical Aperture (NA) is defined by the maximum allowable entrance angle, and indicates the light gathering efficiency of the fiber.

FIBER BUNDLES

**SINGLE
FIBERS**

**MULTI-FIBER
BUNDLES**

**MULTI-MULTI-
FIBER BUNDLES**

Depending on the construction method they can be used for illumination or image conduits

Hexagonal (close) packed array fiber patterns provide maximum packing fraction

Number of pixels (i.e. individual fibers) ranges from 1,000 to 50,000

**INCOHERENT
(ILLUMINATION)
FIBER BUNDLE**

**COHERENT
(IMAGING)
FIBER BUNDLE**

BROKEN FIBERS

BARREL DISTORTION

CHROMATIC ABERRATION

MOIRE' PATTERN

ILLUMINATION - 1

Xenon arc lamps and Tungsten Halogen lamps are the standard light sources used for endoscopy

Some sources employ feedback systems which adjust the light output according to the image brightness

The total light flux accepted by a certain endoscope (for fixed light source output) depends only on the object distance ($1/L^2$)

ILLUMINATION - 2

Light cables include (coherent) glass fiber bundles, or liquid guides, of typical sizes 3 to 5mm

The illumination channel is constructed of glass or plastic fibers or incoherent fiber bundles

The spectroscopic characteristics of the entire illumination chain is important for good color performance

Dual output sources or bifurcated light guides can be useful for cases requiring 2 scopes (mother-daughter), such as falloposcopy & CBD exploration

ENDOSCOPIC CAMERA

Solid State CCD Technology
Performs Sampling of the Image
Analog Device (accumulates/stores
charges that are proportional to
the reflected light
Typical number of pixels 350,000
Rectangular, representing the 4:3
Aspect Ratio of standard TV
Typical Formats: 1/2" (8mm), 2/3" (11mm)
Ease of operation/extended life/
small size/no lag/low power consumption
Filtered Line to eliminate RF Interference

INTEGRATED ENDOSCOPIC CAMERA

LIGHT WEIGHT

SMALL

STERILIZABLE

COMPOSITE, Y-C, RGB OUTPUTS

AUTO GAIN CONTROL (AGC)

CCD Camera vs. Fiber Optic Bundle

- CCD and CMOS chips are now small enough to fit at the working end of endoscopes
- A combination of LED and/or fiber optics is still required to deliver light to the tissue
- CCDs are more durable than fiber optics
- CCDs are difficult to package below 4 mm²
- In smaller scopes, fiber optic bundles are still preferred.

ENDOSCOPIC PROCEDURES

USING THE BODY'S OWN CHANNELS, PHYSICIANS CAN VIEW THE DISEASED SITE AND TREAT IT

BY ELIMINATING THE NEED FOR OPEN SURGERY, ENDOSCOPY REDUCES PAIN, IMPROVES HEALTHCARE & REDUCES COSTS

TIME RESOLVED SPECTROSCOPY (TRS)

PHOTBLEACHING

THE FLUORESCENT PROPERTIES OF TISSUE CAN CHANGE WITH EXPOSURE TO LIGHT. THIS PROCESS, KNOWN AS PHOTBLEACHING, OCCURS OVER THE SECONDS TO MINUTES TIME SCALE AND IS AFFECTED BY THE CHEMICAL ENVIRONMENT OF THE FLUOROPHORE.

INTRODUCTION 1

PHOTOBLEACHING OF FLUORESCENCE IS A DYNAMIC PROCESS IN WHICH FLUORESCENT MOLECULES UNDERGO CHEMICAL ALTERATION UPON EXPOSURE TO LIGHT, AND THUS LOSE THEIR ABILITY TO FLUORESCENCE.

IN GENERAL IT RELATES TO A NUMBER OF USUALLY-NONRADIATIVE DEEXCITATION PATHWAYS WHICH ARE AVAILABLE TO THE MOLECULES DURING THE EXCITATION-DEEXCITATION CYCLE.

INTRODUCTION 2

PHOTBLEACHING IS IMPLICATED TO A LESSER OR GREATER DEGREE IN ANY FLUORESCENCE BASED TECHNIQUE & PLAYS AN IMPORTANT ROLE IN A NUMBER OF BIOLOGICAL APPLICATIONS:

QUANTITATIVE FLUORESCENCE MICROSCOPY

LOSS OF CONTRAST

LIMITED NUMBER OF IMAGES

PHOTODYNAMIC THERAPY

DOSIMETRY

MONITORING

FLUORESCENCE TISSUE IDENTIFICATION

RATIOMETRIC TECHNIQUES

MATERIALS AND METHODS 1

ANIMAL MODEL

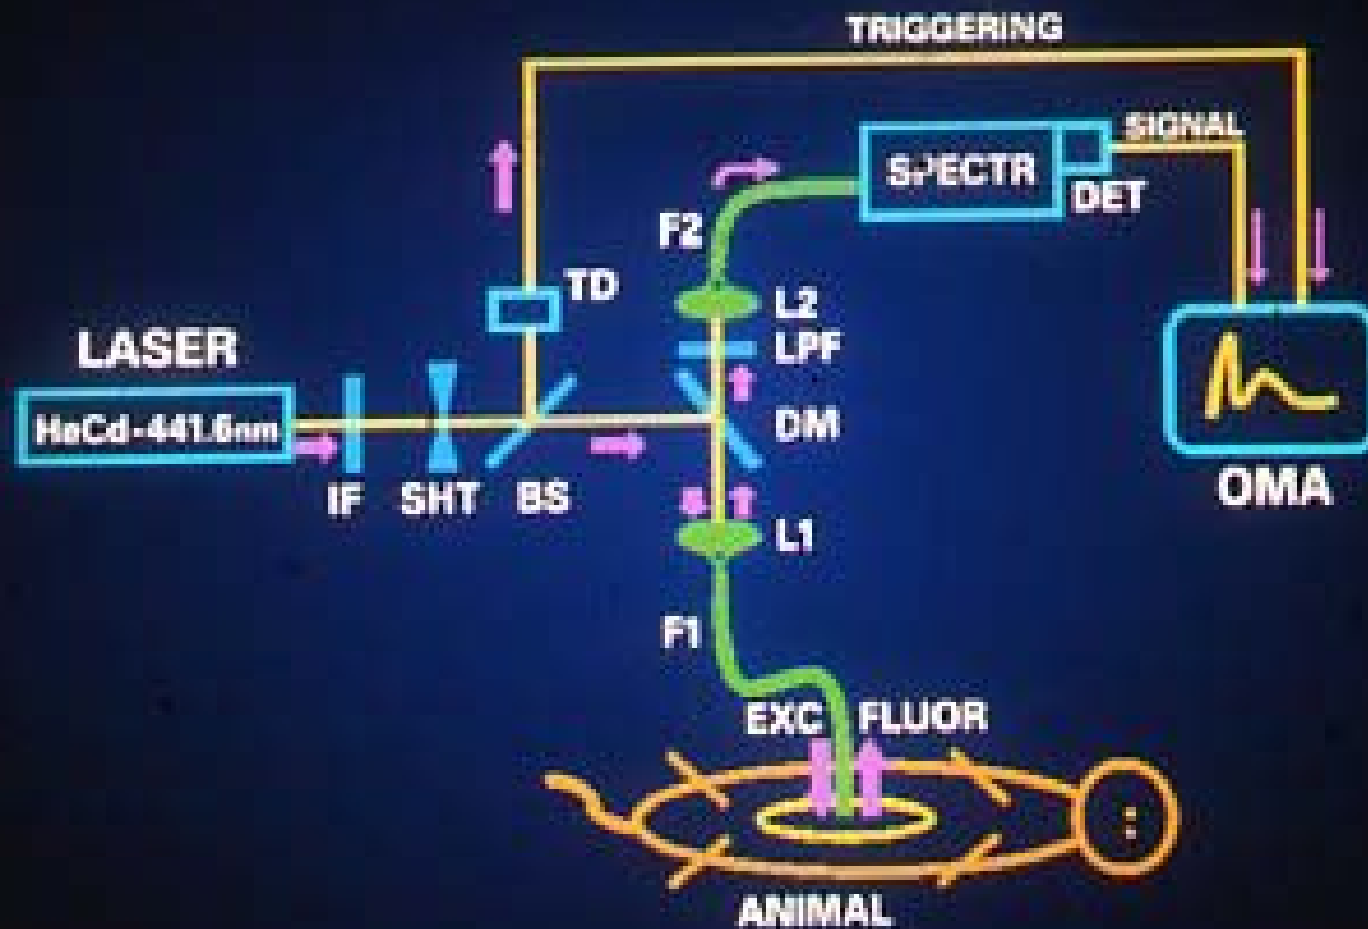

LOBUND WISTAR RATS (N-19)

INFLAMMATORY (1⁺, 2⁺, 3⁺)

METASTATIC-MOSTLY VIABLE (<50% NECROSIS)

METASTATIC-MOSTLY NECROTIC (>50% NECROSIS)

TIME CONSTANT T2

(SLOW COMPONENT)

RESULTS

AVERAGE DECAY PARAMETERS ACROSS ALL SITES

	A_0	A_1	A_2	τ_1 [SEC]	τ_2 [SEC]
NATIVE	0.55	0.27	0.18	0.96	10.4
BPD-MA	9.16	0.21	0.63	1.5	14.8

CONCLUSIONS

FLUORESCENCE PHOTOBLEACHING FOLLOWS SECOND ORDER DYNAMICS IN WHICH THE DECAY CONSTANTS DIFFER BY APPROXIMATELY AN ORDER OF MAGNITUDE FOR BOTH NATIVE AND BPD-MA FLUORESCENCE

CONCLUSIONS

OVERALL, THE AUTOFLUORESCENCE DECAYS FASTER THAN THE DYE FLUORESCENCE. HOWEVER, IT PHOTOBLEACHES LESS THAN DYE FOR THE SAME IRRADIATION PERIOD.

BIOLOGIC SPECTROSCOPY

THE LIGHT SCATTERING AND ABSORPTION PROPERTIES OF TISSUE CAN BE DETERMINED USING BROADBAND (WHITE LIGHT) ILLUMINATION. THE REFLECTED LIGHT IS COLLECTED, SPECTRALLY SORTED AND MEASURED AT MULTIPLE PIXELS WITHIN A GIVEN IMAGE.

BIOLOGIC SPECTROSCOPY

LIGHT INPUT EXCITES TISSUE

**TISSUE EMITS LIGHT AT LONGER
WAVELENGTHS**

**DIFFERENCES IN TISSUE TYPES PRO-
DUCE DIFFERENT EMISSION PATTERNS**

**PATTERN RECOGNITION IS KEY STEP
IN DEVELOPING SPECTROSCOPIC
CONTROL SYSTEM**

BIOLOGIC SPECTROSCOPY

DIFFERENCES IN TISSUE ABSORPTION CHARACTERISTICS PROVIDE MULTIPLE CONTRAST MECHANISMS WITHIN THE IMAGE. AREAS WITH SIMILAR SPECTRAL FEATURES CAN BE IDENTIFIED, SORTED AND DIFFERENTIATED FROM OTHERWISE NORMAL APPEARING TISSUE.

BIOLOGIC SPECTROSCOPY

HISTORICAL PERSPECTIVE

- Pre 1900 - Development of the spectrometer**

IMAGING SPECTROSCOPY

ADVANCED SPECTRAL IMAGING HAS DEVELOPED A MULTI-SPECTRAL IMAGER BASED ON A SIGNAC INTERFEROMETER. THE DEVICE PERMITS ACQUISITION OF A COMPLETE SPECTRA FROM 370nm TO 1000nm FOR EVERY PIXEL IN THE CCD IMAGER. APPROXIMATELY 10 SECONDS IS REQUIRED PER IMAGE. SPECTRAL RESOLUTION IS 3nm AT 400nm AND 10nm AT 1000nm. SOFTWARE ALLOWS RAPID COMPARISON OF ANY SELECTED PIXEL WITHIN AN IMAGE & COMPARISONS TO OTHER IMAGES.

IMAGING SPECTROSCOPY

**WILL IMPROVE THE ABILITY TO
DETECT OCCULT MALIGNANCIES**

**WILL IMPROVE THE DIAGNOSIS OF
VISCERAL ORGAN ESCHERIA**

**WILL DRAMATICALLY ALTER THE
CLASSIFICATION AND TREATMENT
OF RETINAL DISEASES**

OCT

The development of ultrafast laser sources led to the invention of a new imaging modality called Optical Coherence Tomography (OCT).

It is the optical analogue of ultrasonic imaging. Ultra short (femtosecond) light pulses reflect off of layers with differential refractive indexes. The resulting interference patterns are processed to create an image

OPTICAL COHERENCE TOMOGRAPHY HAS BEEN PIONEERED BY FUJIMOTO, IZATT, TROMBERG, TIERNEY, BOUMA AND MANY OTHERS.

FEMTOSECOND LASER PULSES ARE USED TO INVESTIGATE TISSUE AND ARE COMBINED WITH A REFERENCE BEAM TO PRODUCE INTERFERENCE PATTERNS. THIS TECHNOLOGY PROVIDES HIGH RESOLUTION IMAGING OF TISSUE AT DEPTHS OF 300-500 μ .

STRATUS OCT RETINAL IMAGER

COMMERCIALIZATION OF OCT TECHNOLOGY WAS PIONEERED BY ZEISS OPTICAL CORP. WHICH DEVELOPED THE FIRST CLINICAL OCT RETINAL IMAGER.

THIS DEVICE ALLOWS OPHTHALMOLOGISTS TO OBTAIN ACCURATE MEASUREMENTS OF THE THICKNESS OF VARIOUS RETINAL LAYERS FOR DIAGNOSTIC PURPOSES.

There has never been an optical diagnostic device with the total range of capabilities available in the Stratus^{OCT™}.

Stratus^{OCT™} is the first advance of its kind to offer optical coherence tomography with in vivo diagnostic imaging, so practitioners can conduct ocular examinations for retinal disease and glaucoma at an unparalleled level of detail and accuracy. Stratus^{OCT™} is the only device that measures RNFL, optic disk and retina. It's one remarkable innovation.

Advanced technology, only available for research . . . until now.

The Stratus^{OCT™} delivers real-time, cross-sectional images of retinal tissue with an axial resolution of 10 microns or less. With the Stratus^{OCT™}, practitioners can avoid more invasive diagnostic procedures and literally see below the surface of the retina. This provides direct measurement of internal retinal structures as an aid in the diagnosis of glaucoma and retinal diseases.

Make clear, informed diagnoses with Stratus^{OCT™}.

Direct cross-sectional images of live tissue allow practitioners to see disease in vivo. More accurate histology means earlier detection and earlier, often presymptomatic, diagnosis of sight-threatening disease.

Cystoid Macular Edema (CME) with multiple cysts. No angiogram needed for diagnosis and follow-up. Cross-sectional confirmation of diagnosis, as seen only with Stratus^{OCT™}.

View the objective data and in vivo evidence of retinal disease.

Stratus^{OCT™} allows practitioners to identify changes in the RNFL which can lead to early detection of glaucoma. And Stratus^{OCT™} provides for RNFL thickness, bilateral analysis and serial analysis.

Stratus^{OCT™} scans do not require dilation which increases patient compliance. Images and data for analysis are available instantly, in vivo, with no biohazard or blood-related risk.

Macular Hole. Measure the dimensions of macular hole. Cross-sectional confirmation of diagnosis.

Real-time, in vivo retinal images enhance your ability to diagnose.

Stratus^{OCT™} allows practitioners to perform accurate diagnosis and measurement of CME, CSR and macular holes with cross-sectional scans of retinal thickness and in vivo histology of tissue. Diagnosis is further enabled by color-coded maps and retinal thickness in microns in nine map sectors.

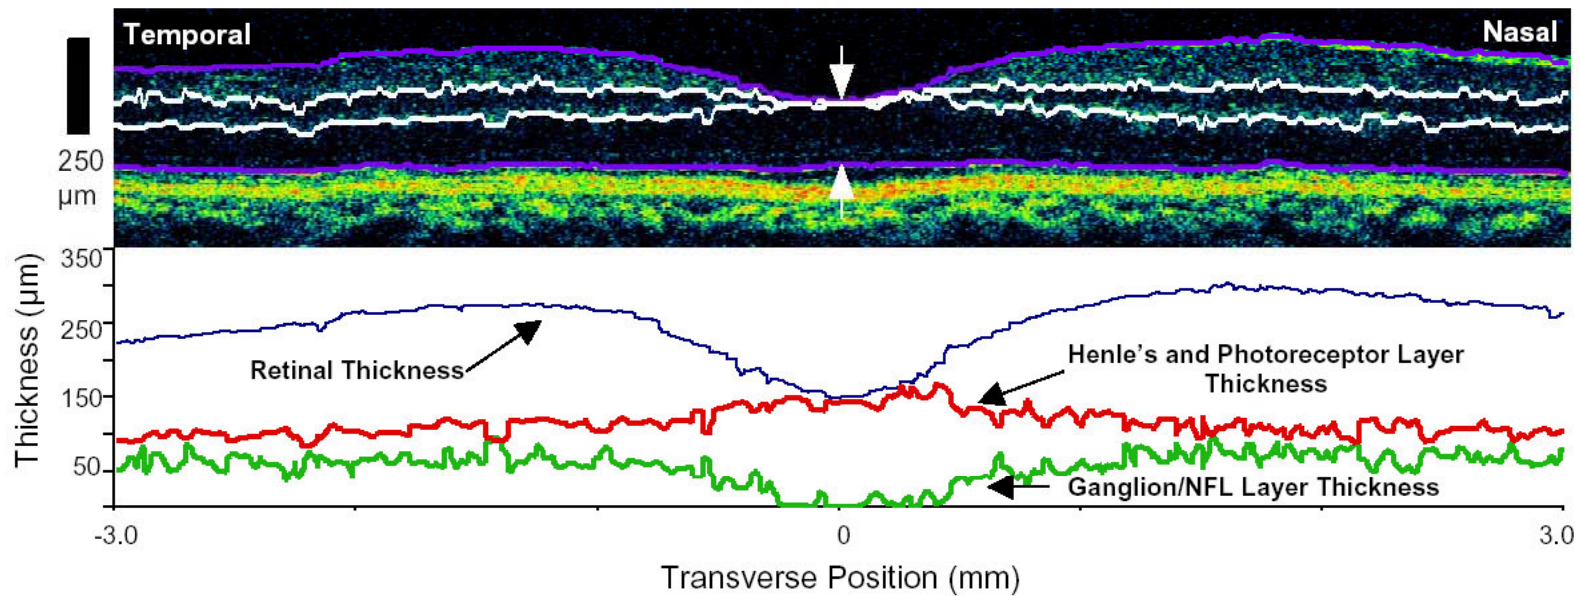

Central Serous Retinopathy Neurosensory detachment at the macula.

THE SUCCESSFUL INTRODUCTION OF RETINAL OCT HAS PROMOTED DEVELOPMENT OF THE TECHNOLOGY FOR MULTIPLE APPLICATIONS.

HIGH RESOLUTION CAN BE OBTAINED BY USING SHORTER PULSES, IMPROVED SCANNING TECHNIQUES AND MORE ACCURATE IMAGE RECONSTRUCTION ALGORITHMS.

HIGH RESOLUTION OCT OF RETINA

Ultrahigh resolution allows for an unprecedented visualization of intraretinal structures which may be quantified to provide an objective measure of retinal disease.

RED: 540 nm
GREEN: 580 nm

**INTENSITY-MAPPED
BAND RATIO:
540nm/580nm**

THE DATA PRESENTED IN THE PREVIOUS SLIDES WAS OBTAINED USING POINT SPECTROSCOPY. A SINGLE FIBER OPTIC CABLE WAS USED TO EXTRACT INFORMATION FROM A SMALL VOLUME OF TISSUE. WHILE ACCURATE, THIS TECHNOLOGY IS TOO SLOW FOR ENDOSCOPIC APPLICATIONS.

IT IS POSSIBLE TO DEVELOP A LIFETIME IMAGING SYSTEM WHICH USES LIFETIME AND WAVELENGTH DATA TO GENERATE CONTRAST MAPS FOR CANCER DETECTION.

HYPERSPECTRAL IMAGING CAN USE EITHER SINGLE OR MULTIPLE EXCITATION SOURCES TO STIMULATE FLUORESCENCE EMISSIONS FROM THE TISSUE.

THE EMITTED FLUORESCENCE IS CAPTURED AND ANALYZED FOR EVERY POINT IN THE IMAGE, YIELDING MAPS OF RELATIVE INTENSITIES. THESE DATA CAN THEN BE USED TO PREDICT THE PRESENCE OR ABSENCE OF CANCERS.

HYPERSPECTRAL IMAGING

**Standard
Laparoscopic
View of Pelvis**

**Fused
Laparoscopic and
Hyperspectral
Image**

**Fused
Laparoscopic, LIFS
and Hyperspectral
Image**

TRLIFS

Hyperspectral imaging to date has not achieved sufficient sensitivity and specificity to eliminate the need for tissue biopsy. In an effort to improve diagnostic accuracy multiple investigators have studied various forms of time resolved fluorescence spectroscopy in an effort to overcome these limitations.

TIME RESOLVED LASER INDUCED FLUORESCENCE SPECTROSCOPY (TRLIFS)

**THE MEASUREMENT OF THE TIME EVOLUTION
AND INTENSITY OF FLUORESCENCE SIGNALS.
MULTIPLE TECHNIQUES ARE AVAILABLE FOR
COLLECTION OF BOTH POINT AND IMAGING
DATA. THE ENORMOUS QUANTITY OF DATA
COLLECTED REQUIRES SUBSTANTIAL COM-
PUTING POWER AND ANALYSIS ALGORITHMS.**

FLUORESCENCE MEASUREMENTS

μ_a comp.

μ_s λ

$\cos\langle\theta\rangle$ δ

308 \rightarrow 80-100 μm

325 \rightarrow 150-200 μm

475 \rightarrow 300-400 μm

◆ Tissue fluorescence

$$E_f = \int_{\text{volume}} (Exc)(Conv)(Esc)dV$$

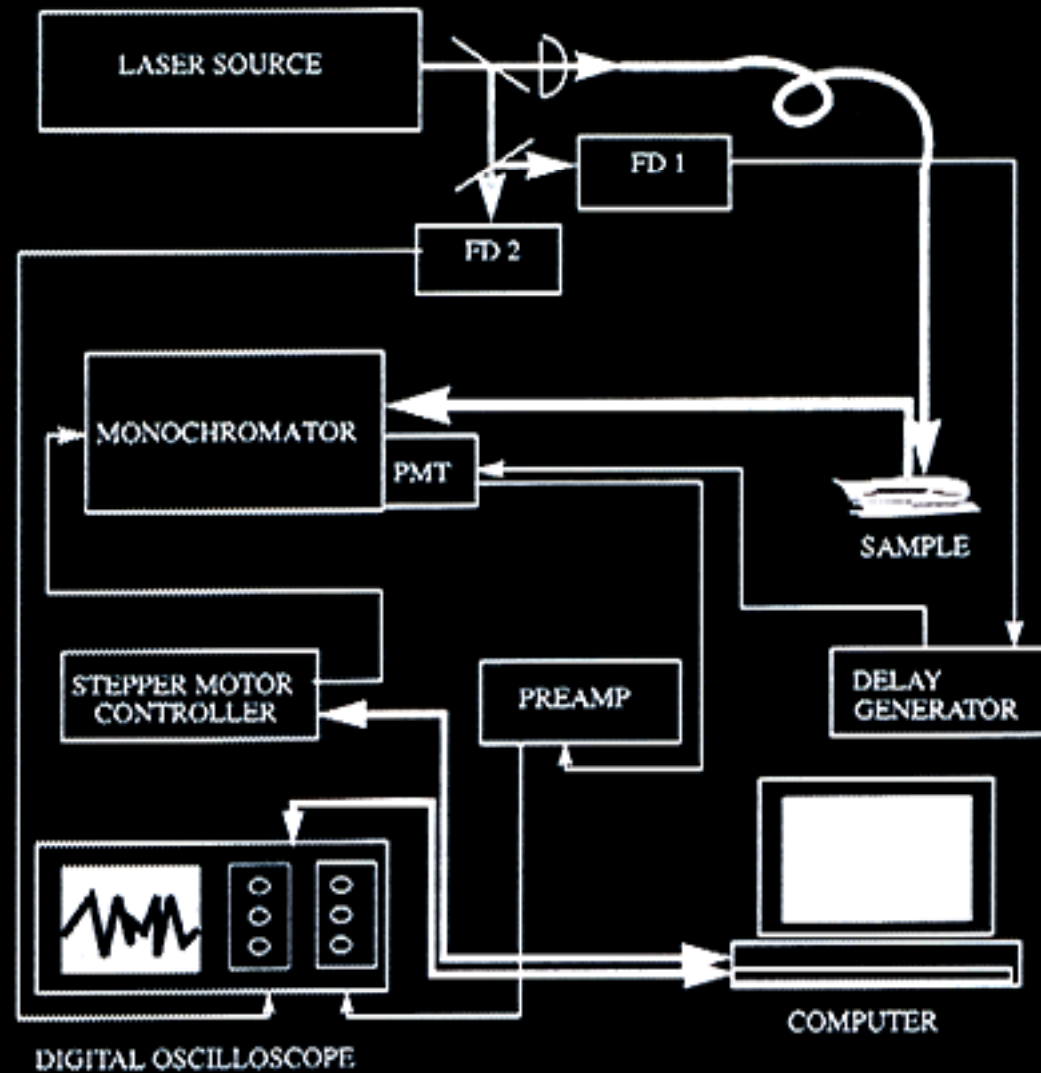

$$E_f = \int_{\text{volume}} (E_0\phi_{ex})(\mu_a\Phi)(\phi_{em})dV$$

$$E_f = E_0\epsilon C\Phi \int_{\text{volume}} \phi_{ex}\phi_{em}dV$$

1. penetration of excitation light
2. absorption \Rightarrow conversion to emission
3. escape of emission

EXPERIMENTAL SETUP

- ◆ **Data pre-processing**

- background noise correction
- laser energy fluctuations correction

- ◆ **Recover spectral emission from time-resolved spectra**

- ◆ **Fluorescence IRF deconvolution**

- Fluorescence convolution integral

$$y(t) = \int_0^{\infty} I_f(\tau)x(t-\tau)d\tau$$

$$y(n) = \sum_m I_f(m)x(n-m) \quad \text{Discrete-time}$$

- ◆ **Statistical analysis**

- Analysis of variance (ANOVA)
- Post-hoc comparison test (Student-Newman-Keuls)

◆ IRF deconvolution

- multiexponential decay (*a priori* postulated functional form)

$$I_f(t) = \sum_{i=1}^n a_i e^{-t/\tau_i}$$

- expansion over the discrete-time Laguerre basis

$$I_f(m) = \sum_j c_j b_j(m, \alpha)$$

$$b_j(m) = \alpha^{\frac{(m-j)}{2}} (1-\alpha)^{\frac{1}{2}} \sum_{k=0}^j (-1)^k \binom{m}{k} \binom{j}{k} \alpha^{j-k} (1-\alpha)^k, (m \geq 0) \quad j=4$$

- least-square iterative reconvolution technique

$$\chi^2 = \sum_{n=1}^N w_n [y_m(n) - y_c(n)]^2$$

$\longrightarrow a_i, \tau_i$
 $\longrightarrow \alpha, c_j$

THE DATA PRESENTED IN THE PREVIOUS SLIDES WAS OBTAINED USING POINT SPECTROSCOPY. A SINGLE FIBER OPTIC CABLE WAS USED TO EXTRACT INFORMATION FROM A SMALL VOLUME OF TISSUE. WHILE ACCURATE, THIS TECHNOLOGY IS TOO SLOW FOR ENDOSCOPIC APPLICATIONS.

IT IS POSSIBLE TO DEVELOP A LIFETIME IMAGING SYSTEM WHICH USES LIFETIME AND WAVELENGTH DATA TO GENERATE CONTRAST MAPS FOR CANCER DETECTION.

**TIME RESOLVED LASER INDUCED
FLUORESCENCE SPECTROSCOPY
(TR-LIFS) CAN DIFFERENTIATE
COLLAGEN FROM ELASTIN AND
IDENTIFY VARIOUS LIPID
COMPONENTS OF TISSUE**

USING UV EXCITATION, SAMPLE VOLUME IS SMALL AND THEREFORE, RESOLUTION IS HIGH. THE TECHNIQUE REQUIRES OPTICAL ILLUMINATION OF THE TARGET TISSUE, EITHER THROUGH A MICROSCOPE OR A FIBER OPTIC PROBE.

CONCLUSIONS

BIOLOGIC SPECTROSCOPY HAS BEEN SUCCESSFULLY APPLIED FOR OXYGEN SATURATION DETERMINATION & METABOLYTE ANALYSIS

NEWER TECHNIQUES, LIFS, TR-LIFS AND IMAGING SPECTROSCOPY ARE NOW AVAILABLE. CLINICAL TRIALS OF THESE MODALITIES ARE NOW UNDER WAY. THE VALUE OF THESE TECHNIQUES WILL DEPEND UPON THE COST OF THE INSTRUMENTATION, THE SENSITIVITY AND SPECIFICITY OF THE MEASURING SYSTEM AND ITS EASE OF USE.
